## International Journal of Sustainable Development and Planning

**IIETA** International Information and  
Engineering Technology Association

*Advancing the World of Information and Engineering*

ISSN: 1743-7601 (Print) E-ISSN: 1743-761X(Online)

**International Journal of Sustainable Development and Planning (IJSDP)** is an interdisciplinary journal covering the subjects of environmental design and planning, environmental management, spatial planning, environmental planning, environmental management and sustainable development in an integrated way as well as in accordance with the principles of sustainability. At the beginning of the 21st century, despite major scientific and technological accomplishments, the struggle for a cleaner environment as well as for the rational organization of space is not settled. It is clear to us that environmentalists, planners, policy makers, engineers and economists have to work together in order to ensure that environmental protection, spatial co-ordination and economic development could all be achieved without compromising the ability of future generations to meet their own requirements. In recent years, an increase in spatial and environmental problems in many countries has led to a crisis in environmental planning and management. The increasing urbanization of the world coupled with the issues of environmental pollution, resource shortages and economic restructuring demand that a lot of effort will be required in order to make our cities sustainable. Moreover, problems of sustainable planning and management are not restricted to urban areas, since rural areas face serious environmental challenges.

The aim of the *International Journal of Sustainable Development and Planning* is to inform its readers about all aspects of environmental planning and management. The journal includes subjects ranging from social to technical environmental management issues, having always as an axis the concept of sustainable planning and development.

### **Focus and Scope**

Papers on the following topics, in accordance with the aims and objectives of the journal, are welcome:

- Sustainable development
- Environmental legislation and policy
- Ecosystems analysis and protection
- Natural resources management
- Coastal planning and policy
- Waste management
- Environmental infrastructure
- Air, water and soil pollution
- Remediation and recovery
- Geo-informatics and the environment
- Environmental impact assessment
- Public safety and security
- Environmental economics
- Tourism and environment
- Social issues
- Rural planning
- Urban planning
- Urban and regional design
- Planning in less-favoured areas
- Regional economics
- Utilities and networks
- Energy resources
- Education and health
- Cultural heritage and architectural issues
- Visual impact and noise pollution

The screenshot shows the Scopus Source details page for the International Journal of Sustainable Development and Planning. The page includes the journal title, Scopus coverage years (2006 to Present), publisher (International Information and Engineering Technology Association), ISSN (1743-7601) and E-ISSN (1743-761X), subject areas (Social Sciences: Geography, Planning and Development; Environmental Science: Management, Monitoring, Policy and Law; Energy: Renewable Energy, Sustainability and the Environment), and source type (Journal). It also features a navigation bar with 'Author Search', 'Sources', 'Create account', and 'Sign in'. The main content area displays 'Source details' with a 'Feedback' and 'Compare sources' link. A table on the right shows performance metrics: CiteScore 2021 (1.8), SJR 2021 (0.284), and SNIP 2021 (0.699). At the bottom, there are links for 'View all documents', 'Set document alert', 'Save to source list', and 'Source Homepage'.

### ABSTRACT

**Received:** 28 November 2022

**Accepted:** 10 March 2023

#### Keywords:

dividend policy model, liquidity, profitability, dividend payout ratio, return on assets, debt to equity ratio, current ratio, agriculture sector

Against the backdrop of the existence of a dividend policy that can provide investors with a variety of signals, the objective of this study is to determine the dividend policy in the Indonesian agricultural sector, given the sector's pronounced volatility between 2014 and 2021. This is what causes the agricultural sector to experience the greatest volatility compared to other sectors. This research develops a dividend policy model with moderating variables, namely liquidity, and mediating variables, namely profitability, in response to a number of gaps in the existing literature. The method employed is quantitative explanation with purposive sampling technique. This study employs path analysis by means of the SEM method and STATA version 14. The results indicate that leverage and firm size have a negative impact on dividends, while profitability has no bearing on dividend policy. Other results indicate that leverage has no effect on profitability, while firm size has a negative effect. The failure of the moderation and mediation tests is caused by the absence of profitability's effect on dividends.

## 1. INTRODUCTION

The dividend policy has been demonstrated to stimulate investors. Diverse stimuli provided by the company's dividend policy can influence the decisions and interests of investors. In return for their investment in the company's shares, shareholders receive dividends, which represent a fraction of the business's profits [1]. Dividend policy refers to the determination of how much dividend will be distributed to investors and ratio of dividends paid to stockholders as a performance metric. Investors focus on dividend policy as an indicator of company performance and management's commitment to the company's long-term viability [2].

Sumber: Indonesian Stock Exchange Website.

**Figure 1.** Graph of the dividend payout ratio

Figure 1 depicts the evolution of the average dividend payout ratio for nine company sectors in Indonesia from 2014 to 2018. The nine company sectors exhibited fluctuations, as demonstrated by this graph. In 2015, however, the agricultural sector marked in light blue experienced extreme fluctuations, falling to -86.78% from 33.87% in 2014. This is what caused

the agricultural sector to experience the greatest volatility compared to other industries.

The dividend payout ratio for agricultural businesses reached a value of -86.78 percent in 2015, despite the fact that a few of these businesses had continued to pay dividends despite experiencing a decline in profitability. Related to 2017 data from the Indonesian Ministry of Agriculture that the Indonesian government made tremendous efforts in 2017 to make the agriculture sector one of the economy's pillars and top priority. To increase agricultural exports, the Indonesian government enacted policies such as the export process policy, which allowed exports to go directly to the destination country without passing through a transit country, and increased diplomatic relations with China in order to simplify the process of obtaining an export license. Both of these policies were successful in increasing agricultural exports. The gross domestic product of the agricultural industry in 2018 was 1,005.4 trillion Indonesian rupiah, which is an increase over 2017's figure of 968.8 trillion. The agricultural sector has achieved positive growth in gross domestic product, which may have an effect on the ability of agricultural sector firms to pay dividends. As a result of these policies and efforts, greatest volatility occurred in the agricultural industry.

Leverage is one of many elements that have a role in dividend policy. In the event of liquidation, leverage is a metric used to assess the company's ability to meet all of its debts, including current and prospective [3]. According to research by Puspita [4], the dividend payout ratio improves noticeably with increased use of leverage. In contrast, Sabrina [5], provide evidence that the dividend payout ratio suffers when leverage is present.

Firm size also influences dividend policy. Large businesses typically do not experience financial challenges since they have easier access to the capital market, giving them a larger

chance to obtain finance support [6]. It is easier for larger businesses to meet their funding requirements [7]. According to the findings of Nuraini [8], the dividend payout ratio does not vary much with the size of a company. Arfianny [9] suggests that dividend payout ratios are significantly impacted by firm size in a negative way.

Profitability is also mentioned as a factor that affects dividend policy. Using return on assets as a metric, profitability is quantified. The ratio of a company's earnings to its total assets demonstrates its ability to turn a profit after taxation [10]. According to the findings of Chandra and Junita [11], Increasing dividend payment ratios are one of the most direct results of increased profits. The company's performance and profitability are capable of increasing the dividend payout ratio [12-14]. In contrast, Nurwani [15] found that dividend payout ratio is significantly impacted by profitability in a manner that is counterproductive.

Profitability has significant significance for the company as a basis for evaluating its condition, performance, and performance. The company's liabilities are one of the factors that influence its profitability. There are numerous methods for determining a company's level of liability, one of which is the debt-to-equity ratio. According to the findings of another study, carried out by Wikardi and Wiyani [16], using leverage has a large and detrimental effect on return on assets. Gunde et al. [17] discovered that leverage significantly increases return on assets. The results of are in agreement with Pramesti et al. [18], who concluded that company obligations have a positive effect on company profitability.

According to research by Pradnyanita et al. [19], the size of a company is used to indicate whether the company's equity is increasing or decreasing. According to Suryati and Yetti [20] and Kausar [21], the larger a company is, the higher its profits tend to be, as measured by return on assets. These findings are supported by Pramesti et al.'s assertion that company size is capable of increasing the return on assets ratio [18]. Contrast these findings with those of Lorenza et al. [22], who found that firm size has no effect on profitability as calculated based on return on assets.

This research employs return on assets ratio (ROA) as a mediating variable. According to the findings of Rohaeni and Ma'mun [23], the return on assets ratio cannot mediate the effect of leverage on the dividend payout ratio.

This research makes use of the current ratio as a moderating variable. The current ratio is the ratio of current assets to current liabilities and is used to evaluate a company's liquidity [10]. According to research by Salsabilla and Isbanah [24], liquidity as measured by the current ratio can moderate dividend policy profitability. Different results were proposed by Yunisari and Ratnadi [25], who claimed that the current ratio, an indicator of liquidity, had no bearing on profitability to dividend policy.

The dividend payout ratio value in Indonesia's agricultural sector has been shown to be on the rise, according to the data presented. research gaps, and the role of liquidity profitability in influencing company dividend policy, this stimulates interest in researching the dividend policy model in agricultural companies in Indonesia by mediating profitability and liquidity moderation. The urgency of this research stems from the need to develop a dividend policy model with profitability as a mediating variable and liquidity as a moderating variable in order to expand the scope of dividend policy research topics.

## **2. LITERATURE REVIEW**

### **2.1 Pecking order theory**

Organizational funding follows pecking order theory. This model requires companies to invest and pay dividends with their own capital [26]. It balances reality [27]. Financial market asymmetric theory popularized the pecking order hypothesis. Managers and investors access information differently, creating a gap [28]. Due to information asymmetry, companies choose internal financing over external, which raises capital costs and affects dividend policies [29].

### **2.2 Firm life cycle theory**

Mueller [30] proposed the Firm Life Cycle Theory regarding dividend payments, which proposes that a company's dividend policy should be dependent on its life cycle. Agency problems are the focal point of Firm Life Cycle Theory. Agency issues are the focus of the company's life cycle theory because agency issues are believed to arise frequently in the early phases of a company's development. During the growth phase of a business, the organization expands and the owner begins to delegate control to the management. Managers will tolerate a greater degree of delegated decision-making and will re-emerge as decision-makers. Management must be able to boost the company's development and profitability in order to maximize shareholder value. There will be agency issues if the management is incapable of delegating effectively and disregards the interests of the shareholders [31].

The life cycle theory provides insight into the emergence of the company's birth phase, growth phase, maturity phase, peak phase, and decline phase. Investors are required to understand the transformation process of companies that will become investment targets [32].

### **2.3 Dividend policy**

Stockholders are rewarded for their investment in a firm by receiving a dividend, which is a portion of the company's profits [1]. In the end, the company's decision regarding the number of dividends to distribute to investors is known as the dividend policy, which can be quantified using the dividend payout ratio. The dividend payment dynamics in developing country markets differ from those in developed countries due to differences in ownership structures and inadequate legal protection governance [33]. A substitute for legal protection for minority investors is dividends. When a company needs capital and offers attractive terms, it must pay high dividends as a reputation-building measure to alleviate investor concerns and minimize agency issues [34].

### **2.4 Leverage**

The leverage variable, as measured by debt-to-equity ratio which shows a company's ability to meet its obligations based on how much of its capital it uses to pay debts. A rise in debt will reduce the net profit available to shareholders, including dividends, because the obligation to pay debts takes precedence over dividend distribution [35].

Companies prefer to invest using retained earnings and other internal funding sources rather than with external funding sources, as suggested by the pecking order theory.

Consequently, companies with a high level of leverage are highly dependent on retained earnings, which prevents profits from being distributed as dividends [36].

A company's debt equity ratio indicates its stability, which is determined by its ability to pay interest on its debts and pay these debts on time [37].

## 2.5 Firm size

Most of the time, dividends from large companies are bigger than dividends from small companies. This is because it is easier for companies with a lot of assets to get into the capital market. This is consistent with the hypothesis of the life cycle of a company, which states that after a corporation has reached maturity, it tends to have high free cash flow and a low growth rate, so mature companies pay higher dividends than young companies. How easy it is for a company to get money from the capital market can depend on how big the company is. Most small businesses can't get bonds or stocks through organized capital markets [38].

## 2.6 Profitability

The return on asset ratio measures how well a company can use all of its assets to make a profit after taxes. This is what the profitability variable means. Return on assets ratio indicates the efficiency with which a business generates profits. If a company is typically steady or has a higher level of profitability, it has the potential to pay out larger dividends. Nevertheless, if the company's profitability declines, it will be unable to pay dividends to its shareholders. This demonstrates a positive relationship between dividend policy and profitability [11-14]. In light of this, we can draw the conclusion that dividends rise together with the rate of return on a company's assets [39]. Following the hierarchical idea of the pecking order, the order of company funding is from cheapest to most expensive: profit, debt, and issuance of shares. To pay dividends, i.e., profits, corporations will use the cheapest funding [40].

## 2.7 Liquidity

In order to determine whether or not a corporation can meet its short-term obligations, analysts look at the current ratio [10]. This ratio is used as a proxy for a company's capacity to meet its short-term obligations due within a year. It is acceptable and indicative of a healthy company if the current ratio is at or above the average for its industry [41]. If a company's current ratio is high, that means it has plenty of cash on hand.

# 3. HYPOTHESIS DEVELOPMENT

## 3.1 Leverage and dividend policy

The dividend payout ratio is significantly impacted favorably by leverage [4]. Companies with a high level of leverage are an indication that the company is developing and expanding, necessitating multiple funding sources for all company activities [42].

Facts and other research findings indicate that when a company has more debt or obligations that must be financed, this will automatically result in a reduction of dividends to

shareholders [43]. In order to minimize external funding, companies with high levels of leverage tend to have low dividend payout policies [44]. Reduced dividend payout ratios are a direct result of increased leverage. Consequently, a larger debt-to-equity ratio has a negative impact on a company's health, and a higher debt composition reduces its dividend-paying capacity [5]. A high level of leverage indicates that a corporation is relying excessively on borrowed funds to fund its operations, it becomes a separate financial pressure, causing it to allocate funds or profits received to pay debts rather than dividends [45]. In addition, conclusive evidence to support the relationship between leverage and dividend policy has not been found [46]. Little or no influence is exerted by leverage on dividend policy [47].

H1: Leverage has a significant effect on dividend policy

## 3.2 Firm size and dividend policy

The dividend policy of a company tends to improve as the company grows in size [38], and raise dividend payments [48]. Companies with a large size are mature and have stable financial health, so they have easy access to external capital markets to obtain external funding and are not wholly reliant on internal funding. Ultimately, these companies can take advantage of their large profits to pay out large dividends. bigger.

Compare these results to those that indicate dividend policy is adversely affected by a company's size [49], because of the increased costs associated with expanding, many large corporations would rather reduce the amount of money they hand out in dividends to their shareholders [7]. In addition, the findings of other studies indicate that size has a favorable relationship with dividends [21]. Apart from that, further results are stated that size of the company does not have any bearing on the dividend policy [50]. There is no correlation between the total value of the assets held by the company and the number of dividends paid out to shareholders [8].

H2: Firm size has a significant effect on dividend policy.

## 3.3 Profitability and dividend policy

Internal financing is the preferred method for financing business activities, followed by debt and equity financing [51]. When a company's profitability rises, it tends to increase dividend distribution [52]. To a large extent, the dividend payout ratio is negatively affected by the return on assets [15]. The dividend payout ratio can be increased by a company's profitability [11-14]. In terms of dividend policy, the dividend payout ratio is stated to be positively influenced by profitability, as measured by return on assets [13].

Another finding shows that dividend payout ratios tend to drop precipitously when profits rise [15], which means that the level of company profitability can affect the amount of dividends that will be distributed to shareholders.

H3: Profitability has significant effect on dividend policy.

## 3.4 Leverage and profitability

Therefore, companies with high leverage have a lower average performance [53] because they have a greater probability of default. According to intriguing findings [54], when it comes to local profits, leverage is detrimental, but when it comes to overseas earnings, it can be rather beneficial.

Contrast these findings with assertion that using leverage

can significantly boost financial returns [17]. According to additional findings [19, 55, 56], that a large reduction in ROA might be expected if leverage is present. The more the leverage, the greater the amount of potentially harmful debt a corporation is carrying.

H4: Leverage has significant effect on profitability.

### 3.5 Firm size and profitability

Growing businesses tend to be more successful than smaller ones, so the larger the company, the greater its profitability [20]. The larger the corporation, the more it can accomplish economically. So that large businesses are more likely to generate greater profits [57].

The size of a company has a negative effect on profitability, according to another finding [58]. However, contrary to what was expected, business size did not significantly affect profitability as assessed by return on assets [22], we find the opposite to be true. Profitability generated by a business is unaffected by the size of the business [59].

H5: Firm size has significant effect on profitability.

### 3.6 Leverage, profitability, and dividend policy

The obligation to pay debts takes precedence over the distribution of dividends, so the size of the dividend will be impacted when there is an increase in the amount of debt [35]. It is generally agreed that return on assets cannot act as a buffer between leverage and the dividend payout ratio [60]. When a corporation's earnings are high enough to encourage an increase in dividend payments, with the presumption that an increase in a company's profits will serve as a trigger for the company to increase the number of dividends distributed to shareholders. Companies that are able to generate profits from the results of both internal financing and external financing in the form of debt will also have the ability to affect the size of dividend distributions [61].

H6: Profitability mediates the effect of leverage on dividend policy.

### 3.7 Firm size, profitability, and dividend policy

It seems that profit, as calculated by return on assets, can moderate the effect of firm size on the dividend payout ratio [62]. This contradicts the conclusion [23] that profitability assessed by return on assets cannot mediate the effect of firm size on the dividend payout ratio. This indicates that a company's size and profitability are not sufficient to guarantee that it will issue cash dividends.

H7: Profitability mediates the effect of firm size on dividend policy.

### 3.8 Profitability, liquidity, and dividend policy

The liquidity shown by the current ratio can mitigate the dividend payout ratio's impact on profitability [24]. Contrary to the results of research which suggests that liquidity as described by the current ratio cannot moderate profitability on dividend policy [25]. Good company liquidity conditions are expected to maintain its performance and develop its business and motivate management to pay dividends. Therefore, liquidity will be a good link between company profitability and dividend policy [63].

H8: Liquidity mediates the effect of profitability on

dividend policy.

The image below depicts the study's theoretical underpinnings and key hypotheses:

Figure 2. Research framework

Figure 2 depicts the current research structure. Using data from the Indonesian agricultural sector, this study examines the moderating role of liquidity and the mediating role of profitability between the effect of firm size and leverage on dividends.

## 4. RESEARCH METHODOLOGY

### 4.1 Research method

Quantitative research is defined as a research method that is based on the philosophy of positivism and is used to examine a specific population or sample, collect data using research instruments, and analyze data quantitatively and statistically to test preconceived hypotheses. This research is included in the category of conclusive research with the type of causality research. Path analysis is the analytical method chosen for efforts to solve complex research models involving not only dependent and independent, but also moderating and mediating variables. Path analysis uses STATA software version 14 to answer the relationship between the various variables investigated in this study. Path analysis is beneficial since it permits researchers to dissect or divide the numerous factors influencing a result into direct and indirect components [64].

When path analysis is used to test hypotheses, SEM offers a number of advantages not accessible with conventional techniques. Using a SEM analysis, not only can the descriptive power of alternative models be compared, but the results can also refer to further observations or crucial experiments that may boost comprehension and would not otherwise be conducted. Consequently, not only may SEM be used to assess theories, but also to assist enhance them [65].

### 4.2 Population and sample

This study's population consists of agricultural firms listed on the IDX (Indonesian Stock Exchange) between 2014 and 2021. This study's population consists of 25 agricultural firms. This study employs a non-probabilistic purposive sampling technique with the following sample criteria: (1) agricultural companies listed on the Indonesia Stock Exchange between 2014 and 2021; (2) companies that uploaded consecutive financial reports for 2014-2021; and (3) agricultural companies that paid dividends at least three times during 2014-2021. The purposive sampling method was selected since not all agricultural enterprises typically pay dividends during the

time period of the study. As a consequence of this, the inclusion of the third criterion results in a population of 25 companies having only 10 companies left to sample. In addition, the reasons for selecting purposive sampling include its low cost, its usability, and the fact that researchers can use it to support selections made according to analytical, logical, or theoretical criteria [66].

Eight years' worth of study resulted in the collection of eighty sets of panel data, all of which were then analyzed using the STATA program. Documentation, more specifically secondary data collection in the form of annual financial reports acquired from the Indonesia Stock Exchange, was the technique of choice for the data collection process.

**Table 1.** Description of variables and measurements

No	Dependent Variable	Measurement
1.	Dividend Policy	Dividend Payout Ratio (DPR) = Earnings Per Share/Dividend Per Share
	<b>Independent Variable</b>	
2.	Leverage	Debt Equity Ratio (DER) = Total Debt/Total Equity
3.	Firm Size	Size = Ln (Total Asset)
	<b>Moderating Variable</b>	
4.	Profitability	Return on Asset (ROA) = Earnings After Tax/Total Asset
	<b>Mediating Variable</b>	
5.	Liquidity	Current Ratio = Current Asset/Current Debt

Table 1 depicts the variables utilised in the study, namely dividend policy, leverage, firm size, profitability, and liquidity, along with specific measurements for each variable.

## 5. RESULTS AND DISCUSSION

### 5.1 Descriptive statistics

According to the descriptive statistics, the dividend payout ratio has an average value of 0.263, with a maximum of 10.32 and a minimum of -6.43. This value indicates that the average agricultural company distributes 26.3% of its net income as dividends. The investment variable has a standard deviation of 1.440, or 144% (above 100%), indicating that the distribution of dividend payout ratio (DPR) data between observations is variable.

The average leverage value is 1.039. The maximum leverage value is 2.68 and the minimum leverage value is 0.15. This value indicates that, on average, agricultural companies use more debt than equity to fund their operations. The investment variable has a standard deviation of 0.735, or 73.5 percent (below 100%), indicating that the distribution of leverage data between observations is not overly variable.

The average size of agricultural companies in Indonesia is 16.273, with the smallest size being 14.44 and the largest being 137.51. This indicates that agricultural companies in Indonesia are of comparable size, as the difference between the minimum and maximum values is small.

ROA has a mean value of 0.053 with a maximum value of 0.18, and a minimum value of -0.02. This value indicates that

the average agricultural enterprise can generate a net profit of 5.3 percent utilizing its total assets. The investment variable has a standard deviation of 0.043, or 4.3% (below 100%), indicating that the distribution of ROA data between observations is not overly variable.

As measured by the current ratio (CR), the average liquidity of agricultural companies is 2.209, with a maximum of 7.44 and a minimum of 0.50. This demonstrates that the typical agricultural company has excellent liquidity. The investment variable has a standard deviation of 1.831, or 183.1% (above 100%), indicating that the distribution of CR data between observations varies.

**Table 2.** Descriptive statistics

Var.	Obs.	Mean	St Dev.	Min	Max
DPR	80	0.263	1.440	-6.43	10.32
LEV	80	1.039	0.735	0.15	2.68
SIZE	80	16.273	0.763	14.44	17.51
ROA	80	0.053	0.043	-0.02	0.18
CR	80	2.209	1.831	0.58	7.44

Table 2 depicts descriptive statistics for the research data, including the number of observations, mean, standard deviation, minimum, and maximum values.

### 5.2 Regression analysis

The coefficient for the p-value of leverage on dividends is -2.34, as shown in Table 3. It is proven that leverage significantly reduces the dividend payout ratio (DPR). Al-Malkawi [67], Gonzalez et al. [68], Al-Malkawi [69], Hashemi [70], John and Muthusamy [71], Gupta and Banga [72], and Al-Shubiri [73] all found similar results. According to them, the company's operational activities that payments to shareholders are minimal. The size of the company's debt will reduce its dividend-paying capacity.

The coefficient for the p-value of firm size to dividends is -2.34, as shown in Table 3. In accordance with the findings of Banerjee [51], Al-Shubiri [73], and Afza and Mizan [74], this result is conceivable due to the fact that it is stated that large companies can allocate their funds to multiple investments or future expansion, thereby reducing the likelihood of dividend payments. Also contributing to this outcome is the fact that a larger company will incur greater operational costs as it grows, which will inevitably reduce the dividend payout to shareholders. According to Eltya et al. [75], the stakes are higher when a corporation has more assets at risk.

Profitability has no effect on dividend policy, according to the study's findings, because companies with high profits tend not to pay dividends and instead retain these profits as a future investment model. These findings are consistent with the findings of Afza and Mizan [74], Adil et al. [76], and Anil and Kapoor [77], who concluded that profitability has no effect on dividend policy, as measured by the dividend payout ratio.

The study found that using debt did not increase profits, as the size of a company's debt cannot affect profitability. According to research conducted by Maulita and Tania [78], Dissanayake [79], Velnampy and Nires [80], and Amidu [81], leverage has no effect on profitability.

According to the findings, a company's profitability decreases as its size increases, with the explanation that companies must adjust company size and operational costs in order to increase return on assets [53, 54]. The greater the company's size, the greater its scope and economic activity.

Consequently, there is a chance that large companies will generate a smaller profit as well. These findings are consistent with Bilal [82].

The fact that the p-value of the Sobel test for mediation of profitability is greater than 0.050 indicates that profitability cannot serve as a mediator between leverage and dividends. The research of Rohaeni and Ma'mun [23] indicates that ROA profitability cannot mediate the effect of firm size on the dividend payout ratio. This result cannot be separated from the absence of profitability leverage, so the mediation role of profitability cannot be demonstrated.

The fact that the p-value of the Sobel test for mediation of profitability is greater than 0.050 indicates that profitability cannot serve as a mediator between firm size and dividends. This result is consistent with the findings of Rohaeni and Ma'mun [18], who found that ROA profitability cannot mediate the effect of firm size on the dividend payout ratio. This shows that a company's size and profitability are no guarantee that it will pay dividends to shareholders in the form of cash.

The results of the moderated regression analysis (MRA) test of liquidity moderation indicate that liquidity cannot strengthen or weaken the effect of firm size on dividends. According to research conducted by Yunisari and Ratnadi [25], liquidity as described by the current ratio cannot moderate profitability in relation to the dividend payout ratio. This suggests that there will be no rise in dividend payments due to liquidity when company profitability is high and cannot decrease dividend payments when company profitability is low. So, the size of liquidity as measured using the current ratio cannot give a strengthening or weakening effect.

**Table 3.** Hypothesis testing and result

Variables	DPR		ROA	
	Coef	Sig	Coef	Sig

Table 3 depicts the findings from the study's hypothesis testing.

## 6. CONCLUSION

The findings demonstrate that there is conclusive evidence that leverage can have an adverse effect on dividend policy. If an organization has a low debt-to-equity ratio, there is a greater chance that it will pay dividends to shareholders. Investors should favor those kinds of businesses. In order for agricultural businesses to be in a position to boost their dividends, the company's debt should first be paid down. This will result in lower interest costs for the business as well as a

larger portion of profits that dividends are a sort of financial compensation that may be paid out to shareholders. Because it has been demonstrated that the dividend policy of a company tends to decline as it grows larger. The findings of this study are readily apparent from the research data, which indicates that when the company's assets decrease, their dividends increase, while on the other hand, when the company's assets increase, the dividends distributed are lower than they were the year before.

### 6.1 Implications of study

The findings of this study imply, furthermore, that the magnitude of a company's profitability is unable to exert any influence over dividend policy. Additionally, the leverage ratio is unable to exert any influence on the magnitude of the company's profits. Several studies have found that the size of an organization has an impact on its profitability. The company's size can play a major role in how well it is able to run its business and make a profit. Due to the fact that partial profitability did not have an effect on dividends, it was determined that partial profitability could not act as a mediating factor between the effect of firm size and leverage on dividends. The results of this test were reported as being inconclusive. Another significant finding from this investigation demonstrates that liquidity cannot act as a moderator between dividend policy and profitability. The implications of this study's conclusions for agricultural businesses are that they must reduce their wasteful use of assets, which will lead to a decline in corporate profitability and dividends. In order to improve profits and dividend distribution, businesses must truly move swiftly and optimize their assets through competent management.

### 6.2 Limitation and further study

Indonesia's agricultural sector provides minimal data for research. Thus, the conclusions are restricted to the agricultural sector of underdeveloped nations. It is recommended that future researchers perform studies encompassing a greater number of business sectors in both emerging and wealthy nations. Future study should include profitability as the primary determinant influencing dividend policy. Future research can include other variables that can influence dividend policy, such as free cash flow, ownership structure, asset structure, and other variables outside the scope of this study, in order to investigate additional variables that can impact dividend policy. This study employs moderators and restricted mediators to examine the relationship between profitability and liquidity; therefore, it is suggested that additional factors be used to obtain more precise and meaningful findings.
